The CA3280 and CA3280A types consist of two variable operational amplifiers that are designed to substantially reduce the initial input offset voltage and the offset voltage variation with respect to changes in programming current. This design results in reduced "AGC thump," an objectionable characteristic of many AGC systems. Interdigitation, or crosscoupling, of critical portions of the circuit reduces the amplifier dependence upon thermal and processing variables.
The CA3280 has all the generic characteristics of an operational voltage amplifier except that the forward transfer characteristics is best described by transconductance rather than voltage gain, and the output is current, not voltage. The magnitude of the output current is equal to the product of transconductance and the input voltage. This type of operational transconductance amplifier was first introduced in 1969, and it has since gained wide acceptance as a gateable, gain controlled building block for instrumentation and audio applications, such as linearization of transducer outputs, standardization of widely changing signals for data processing, multiplexing, instrumentation amplifiers operating from the nanopower range to high current and high speed comparators. For additional application information on this device and on OTAs in general, please refer to Application Notes: AN6818, AN6668, and AN6077.

## Pinout

## Ordering Information

| PART NUMBER | TEMP. <br> RANGE $\left({ }^{\circ} \mathbf{C}\right)$ | PACKAGE | PKG. <br> NO. |
| :--- | :---: | :--- | :--- |
| CA3280AE | -55 to 125 | 16 Ld PDIP | E16.3 |
| CA3280E | 0 to 70 | 16 Ld PDIP | E16.3 |

## Features

- Low Initial Input Offset Voltage: $500 \mu \mathrm{~V}$ (Max) (CA3280A)
- Low Offset Voltage Change vs $\mathrm{I}_{\mathrm{ABC}}:<500 \mu \mathrm{~V}$ (Typ) for All Types
- Low Offset Voltage Drift: $5 \mu \mathrm{~V} /{ }^{\circ} \mathrm{C}$ (Max) (CA3280A)
- Excellent Matching of the Two Amplifiers for All Characteristics
- Internal Current-Driven Linearizing Diodes Reduce the External Input Current to an Offset Component
- Flexible Supply Voltage Range $\pm 2 \mathrm{~V}$ to $\pm 15 \mathrm{~V}$

## Applications

- Voltage Controlled Amplifiers
- Voltage Controlled Oscillators
- Multipliers
- Demodulators
- Sample and Hold
- Instrumentation Amplifiers
- Function Generators
- Triangle Wave-to-Sine Wave Converters
- Comparators
- Audio Preamplifier

## Application Information

Figures 4 and 5 show the equivalent circuits for the current source and linearization diodes in the CA3280. The current through the linearization network is approximately equal to the programming current. There are several advantages to driving these diodes with a current source. First, only the offset current from the biasing network flows through the input resistor. Second, another input is provided to extend the gain control dynamic range. And third, the input is truly differential and can accept signals within the common mode range of the CA3280.

## Typical Applications

The structure of the variable operational amplifier eliminates the need for matched resistor networks in differential to single ended converters, as shown in Figure 6. A matched resistor network requires ratio matching of $0.01 \%$ or trimming for 80 dB of common-mode rejection. The CA3280, with its excellent common mode rejection ratio, is capable of converting a small $( \pm 25 \mathrm{mV}$ ) differential input signal to a single-ended output without the need for a matched resistor network.

Figure 7 shows the CA3280 in a typical gain control application. Gain control can be performed with the amplifier bias current

FIGURE 4. VOA SHOWING LINEARIZATION DIODES AND CURRENT DRIVE

FIGURE 6. DIFFERENTIAL TO SINGLE ENDED CONVERTER
( $l_{A B C}$ ). With no diode bias current, the gain is merely $g_{M} R_{L}$. For example, with an $\mathrm{I}_{\mathrm{ABC}}$ of 1 mA , the $\mathrm{g}_{\mathrm{M}}$ is approximately 16 mS . With the CA3280 operating into a $5 \mathrm{k} \Omega$ resistor, the gain is 80 .

The need for external buffers can be eliminated by the use of low value load resistors, but the resulting increase in the required amplifier bias current reduces the input impedance of the CA3280. The linearization diode impedance also decreases as the diode bias current increases, which further loads the input. The diodes, in addition to acting as a linearization network, also operate as an additional attenuation system to accommodate input signals in the volt range when they are applied through appropriate input resistors.

Figure 10 shows a triangle wave to sine wave converter using the CA3280. Two $100 \mathrm{k} \Omega$ resistors are connected between the differential amplifier emitters and $V+$ to reduce the current flow through the differential amplifier. This allows the amplifier to fully cut off during peak input signal excursions. THD is appropriately $0.37 \%$ for this circuit.

NOTES:

1. Controlling Dimensions: $\operatorname{INCH}$. In case of conflict between English and Metric dimensions, the inch dimensions control.
2. Dimensioning and tolerancing per ANSI Y14.5M-1982.
3. Symbols are defined in the "MO Series Symbol List" in Section 2.2 of Publication No. 95.
4. Dimensions A, A1 and L are measured with the package seated in JEDEC seating plane gauge GS-3.
5. D, D1, and E1 dimensions do not include mold flash or protrusions. Mold flash or protrusions shall not exceed 0.010 inch ( 0.25 mm ).
6. $E$ and $\mathrm{e}_{\mathrm{A}}$ are measured with the leads constrained to be perpendicular to datum $-\mathrm{C}-$.
7. $e_{B}$ and $e_{C}$ are measured at the lead tips with the leads unconstrained. $\mathrm{e}_{\mathrm{C}}$ must be zero or greater.
8. B1 maximum dimensions do not include dambar protrusions. Dambar protrusions shall not exceed 0.010 inch $(0.25 \mathrm{~mm})$.
9. N is the maximum number of terminal positions.
10. Corner leads (1, $\mathrm{N}, \mathrm{N} / 2$ and $\mathrm{N} / 2+1$ ) for E8.3, E16.3, E18.3, E28.3, E42.6 will have a B1 dimension of 0.030-0.045 inch (0.76-1.14mm).
